Abstract

In this paper an algorithm for the unconstrained and bound constrained minimization problem using second order information is presented. It determines a point satisfying the second order necessary optimality condition. A truncated Lanczos decomposition of the reduced Hessian of the objective function is computed in order to determine three directions of descent, and, if a negative curvature direction is found, a special linesearch method is used. In the case of a bound constrained problem this approach is combined with projected gradient steps to obtain an efficient activation/inactivation strategie. As only matrix-vector-products are needed within the Lanczos algorithm the method is of special interest for large scale problems. The convergence theory is outlined and numerical results are presented.

Key words

Large scale bound constrained minimization, gradient projection step, negative curvature directions, Lanczos algorithm, partial reorthogonalization, line-search methods

1 Introduction

In this paper we consider the problem

$$\begin{aligned} & \text{minimize} && f(x) \\ & \text{subject to} && l_i \leq x_i \leq u_i \quad i = 1, \dots, n. \end{aligned} \tag{BCP}$$

*email: felkel@mathematik.tu-darmstadt.de

We assume $f \in C^3(\mathcal{D})$ with \mathcal{D} an open, convex superset of the feasible box $\Omega_B = \prod_{i=1}^n [l_i, u_i]$. Note that some components of l and u may be infinite. Throughout the paper we assume that for the initial point $x^0 \in \mathcal{D}$ the intersection of the level set

$$\mathcal{L}_f(f(x^0)) \stackrel{\text{def}}{=} \{x \in \mathcal{D} : f(x) \leq f(x^0)\}$$

and the feasible region Ω_B is compact.

In section 2 a method for unconstrained programming problems is outlined. The development of the algorithm and the related convergence theory was done by Heinrich in [Hei85]. He used a spectral or a Bunch-Parlett decomposition of the exact Hessian in order to compute up to three directions of descent. Even for medium scale problems a spectral or a Bunch-Parlett decomposition of the Hessian is “expensive”. A much “cheaper” way to get some information about the spectrum of the Hessian is to use a truncated Lanczos decomposition to obtain some ritzvalues approximating the outer eigenvalues (see [GL89], [Par80b] or [ST85]). This information can also be used to compute directions of descent.

In section 3 the unconstrained minimization technique is combined with a gradient projection method as proposed by Moré and Toraldo in [MT91]. The projected gradient steps are used as a multiple activation/inactivation strategy to identify the set of active variables. Whenever the gradient projection stops on a face of the box the unconstrained minimizer is used to minimize the objective function over the set of free variables. The convergence properties derived in section 2.2 can be used to prove convergence to a point satisfying the second order necessary optimality condition.

Section 4 deals with the implementation of the presented method. Some features to increase stability and effectiveness of the Lanczos algorithm are presented and the termination criteria are given.

Finally the CONSTRAINED AND UNCONSTRAINED TESTING ENVIRONMENT CUTE (see [BCGT97]) is used to solve several small, medium and large scale bound constrained and unconstrained programming problems. The numerical results are presented in section 5. To show the advantage of our method in solving (very) large scale problems the comparison with the limited memory quasi-Newton method LBFGS-B (see [BLNZ95]) is given.

Notation

We denote a diagonal matrix, whose i -th diagonal element is d_i , by $\text{diag}(d_i)$ and x_i denotes the i -th component of a vector x . The index of an element from a sequence of vectors is denoted as a superscript, as in x^k . In the case of a sequence of scalars the index is subscripted, as in σ_l . Whenever the power of a scalar is needed we write the base in brackets. Hence $(x_i^k)^2$ denotes the square of the i -th component of the k -th element in the vector-sequence $\{x^k\}_{k \rightarrow \infty} \subset \mathbb{R}^n$. For a matrix B $B_{\mathcal{A}}$ denotes the matrix made up from columns with indices in \mathcal{A} . The gradient of the objective function f is denoted by the column vector $\nabla f(x)$ and the Hessian of f is $\nabla^2 f(x)$. The eigenvalues of the Hessian (or any other matrix) are given by $\lambda_i(\nabla^2 f(x))$. $\lambda_{\min}(\cdot)$

denotes the minimum eigenvalue. Throughout the paper $\|\cdot\|$ is the Euclidean norm $(x^T x)^{\frac{1}{2}}$ of a vector x .

2 Unconstrained problems

Finding a local solution of the unconstrained minimization problem

$$\text{minimize } f(x) \quad (\text{UCP})$$

can be done by searching a point x^* such that $\nabla f(x^*) = 0$ and $\lambda_{\min}(\nabla^2 f(x^*)) > 0$. This is a sufficient condition. Necessary for a local minimizer is $\nabla f(x^*) = 0$ and $\lambda_{\min}(\nabla^2 f(x^*)) \geq 0$. The algorithm outlined below tries to find a point x^* satisfying the necessary condition.

2.1 Outline of the algorithm

Algorithm 2.1 (UCA)

Given the starting point x^0 , a regularity threshold $\rho > 0$ and a termination parameter $0 < \epsilon \ll 1$. Set $k = 0$ and proceed

Step 1 *Use $-\nabla f(x^k)$ as initial vector to compute a truncated Lanczos decomposition of the Hessian $\nabla^2 f(x^k)$ using maximum of $\bar{\nu}$ Lanczos steps*

$$\begin{aligned} \nabla^2 f(x) Q_\nu^k - Q_\nu^k T_\nu^k &= \beta_{\nu+1} q_{\nu+1} e_\nu^T \\ (Q_\nu^k)^T Q_\nu^k &= I_\nu, \end{aligned} \quad (1)$$

where $\nu \leq \bar{\nu}$ is the actual number of computed Lanczos vectors. Compute the eigenvalues and eigenvectors of the tridiagonal matrix T_ν^k and get the ritzvalues and -vectors

$$Q_\nu^k T_\nu^k (Q_\nu^k)^T = Q_\nu^k V_\nu^k D_\nu^k (Q_\nu^k V_\nu^k)^T = S_\nu^k D_\nu^k (S_\nu^k)^T. \quad (2)$$

$D_\nu^k = \text{diag}((\lambda_i^k)_{i=1,\dots,\nu})$ is the diagonal matrix of the ritzvalues and $S_\nu^k = (s_1^k, \dots, s_\nu^k) \in \mathbb{R}^{n \times \nu}$ is the matrix of the ritzvectors. Determine the index sets $\mathcal{N}_- = \{i : \lambda_i^k < 0\}$ and $\mathcal{N}_{+0} = \{i : \lambda_i^k \geq 0\}$ of negative and non-negative ritzvalues. W.l.o.g. we assume that the ritzvalues are sorted in ascending order $\lambda_1^k \leq \dots \leq \lambda_\nu^k$.

Step 2 *Compute three different directions of descent*

a) *If $|\mathcal{N}_{+0}| \neq 0$ set*

$$d^k \stackrel{\text{def}}{=} -((S_\nu^k)_{\mathcal{N}_{+0}} (\bar{D}_\nu^k)^{-1} (S_\nu^k)_{\mathcal{N}_{+0}}^T) \nabla f(x^k), \quad (3)$$

where $\bar{D}_\nu^k \stackrel{\text{def}}{=} \text{diag}((\max(\lambda_i^k, \rho))_{i \in \mathcal{N}_{+0}})$. If $|\mathcal{N}_{+0}| = 0$ set $d^k = 0$.

b) *If $|\mathcal{N}_-| \geq 2$ set*

$$r^k \stackrel{\text{def}}{=} -(S_\nu^k)_{\mathcal{N}_-} (S_\nu^k)_{\mathcal{N}_-}^T \nabla f(x^k) \quad (4)$$

otherwise $r^k = 0$.

c) *If $|\mathcal{N}_-| \neq 0$ set*

$$z^k \stackrel{\text{def}}{=} s_1^k. \quad (5)$$

otherwise $z^k = 0$.

Step 3 Take a step along these directions using the linesearch algorithm (LSA1) or (LSA2).

a) Let $\Phi_d(t) \stackrel{\text{def}}{=} f(x^k + td^k)$ and compute $\Phi'_d(0), \Phi''_d(0)$. The steplength σ_d is given by

(i) If $\Phi''_d(0) > 0$ then use (LSA1) with

$$(\sigma_d)_0 = \min \left\{ 1, -\frac{\Phi'_d(0)}{\Phi''_d(0)} \right\}.$$

(ii) If $\Phi''_d(0) = 0$ then use (LSA1) with

$$(\sigma_d)_0 = 1.$$

(iii) If $\Phi''_d(0) < 0$ then use (LSA2) with

$$(\sigma_d)_0 = \begin{cases} \|x^k - x^{k-1}\| & \text{if } k > 0 \\ \|d^k\| & \text{if } k = 0 \end{cases}$$

Set

$$x_d^k \stackrel{\text{def}}{=} x^k + \sigma_d d^k. \quad (6)$$

b) Let $\Phi_r(t) \stackrel{\text{def}}{=} f(x_d^k + tr^k)$ and compute $\Phi'_r(0), \Phi''_r(0)$. Use the same scheme as in a) to get a steplength σ_r and set

$$x_r^k \stackrel{\text{def}}{=} x_d^k + \sigma_r r^k. \quad (7)$$

c) Let $\Phi_z(t) \stackrel{\text{def}}{=} f(x_r^k + tz^k)$ and compute $\Phi'_z(0), \Phi''_z(0)$. Use the same scheme as in a) to get a steplength σ_z and define the next iterate

$$x^{k+1} \stackrel{\text{def}}{=} x_r^k + \sigma_z z^k. \quad (8)$$

Step 4 If

$$\|\nabla f(x^{k+1})\| > \epsilon$$

set $k = k + 1$ and continue with **Step 1**

Step 5 If

$$\|\nabla f(x^{k+1})\| \leq \epsilon$$

compute another truncated Lanczos decomposition of the Hessian $\nabla^2 f(x^k)$, using a maximum of $\bar{\nu}$ Lanczos steps and a start vector generated at random. Determine the index sets $\mathcal{N}_- = \{i : \lambda_i^k < 0\}$ and $\mathcal{N}_{+0} = \{i : \lambda_i^k \geq 0\}$ of negative and non-negative ritzvalues.

If $|\mathcal{N}_-| = 0$ stop.

If $|\mathcal{N}_-| \neq 0$ set $k = k + 1$ and continue with **Step 2**. ■

In the algorithm (UCA) we make use of two linesearch algorithms (LSA1) and (LSA2). The first one is the well-known Goldstein-Armijo algorithm (backtracking). The second one is only to be used if the second directional derivative of f with respect to the current direction of descent is negative. In (LSA2) the decrease of the objective will be compared with a concave function (see [Hei85]), instead of a linear one as in (LSA1).

Algorithm 2.2 (LSA1)

Given $x \in \mathcal{D}$, a direction of descent d ($\nabla^T f(x)d \leq 0$), an initial step σ_0 and parameters $0 < \delta_1 < 1$ and $0 < \beta_1 < 1$. Set $j = 0$ and proceed

Step 1 If $\nabla^T f(x)d = 0$ set $\sigma = 0$ and stop.

Step 2 If

$$f(x) - f(x + (\sigma_0 \beta_1^j) d) \geq \delta_1(\sigma_0 \beta_1^j) |\nabla^T f(x)d| \quad (9)$$

set $\sigma = \sigma_0 \beta_1^j$ and stop

Step 3 Set $j = j + 1$ and continue with **Step 2**. ■

Algorithm 2.3 (LSA2)

Given $x \in \mathcal{D}$, a direction of descent $\tilde{v} \neq 0$ with $\nabla^T f(x)\tilde{v} \leq 0$ and $\tilde{v}^T \nabla^2 f(x)\tilde{v} < 0$, an initial step σ_0 and parameters $0 < \delta_2 < \delta_3 < 1$, $0 < \beta_2 < 1$ and $-1 \ll \zeta < 0$.

Define

$$\Phi_v(t) \stackrel{\text{def}}{=} f(x + tv)$$

where $v = \frac{\tilde{v}}{\|\tilde{v}\|}$ and compute

$$\Phi'_v = \nabla^T f(x)v \leq 0 \quad \text{and} \quad \Phi''_v = v^T \nabla^2 f(x)v < 0. \quad (10)$$

Define the control function

$$P(\sigma) \stackrel{\text{def}}{=} \sigma \Phi'_v + \frac{1}{2}(\sigma)^2 \Phi''_v + \zeta(\sigma)^3. \quad (11)$$

Set $j = 0$ and start the procedure at case A,B or C.

Case A If

$$f(x) - f(x + \sigma_0 v) > -\delta_3 P(\sigma_0)$$

continue with **Step A1**.

Step A1 Set $\sigma_{j+1} = \frac{\sigma_j}{\beta_2}$ and $j = j + 1$.

Step A2 If

$$f(x) - f(x + \sigma_j v) > -\delta_3 P(\sigma_j)$$

continue with **Step A1**.

Step A3 If

$$f(x) - f(x + \sigma_j v) > -\delta_2 P(\sigma_j)$$

set $\sigma = \sigma_j$ and stop.

Step A4 Set $\sigma_{j+1} = \frac{\sigma_j + \sigma_{j-1}}{2}$ and $j = j + 1$. Goto **Step AB1**.

Case B If

$$f(x) - f(x + \sigma_0 v) < -\delta_2 P(\sigma_0)$$

or $x + \sigma_0 v \notin \mathcal{D}$ continue with **Step B1**.

Step B1 Set $\sigma_{j+1} = \sigma_j \beta_2$ and $j = j + 1$.

Step B2 If

$$f(x) - f(x + \sigma_j v) < -\delta_2 P(\sigma_j)$$

continue with **Step B1**.

Step B3 If

$$f(x) - f(x + \sigma_j v) < -\delta_3 P(\sigma_j)$$

set $\sigma = \sigma_j$ and stop.

Step B4 Set $\sigma_{j+1} = \frac{\sigma_j + \sigma_{j-1}}{2}$ and $j = j + 1$. Goto **Step AB1**.

Case C If

$$-\delta_2 P(\sigma_0) \leq f(x) - f(x + \sigma_0 v) \leq -\delta_3 P(\sigma_0)$$

set $\sigma = \sigma_0$ and stop.

Step AB1 If

$$-\delta_2 P(\sigma_j) \leq f(x) - f(x + \sigma_j v) \leq -\delta_3 P(\sigma_j) \quad (12)$$

set $\sigma = \sigma_j$ and stop.

Step AB2 If

$$f(x) - f(x + \sigma_j v) > -\delta_3 P(\sigma_j)$$

set

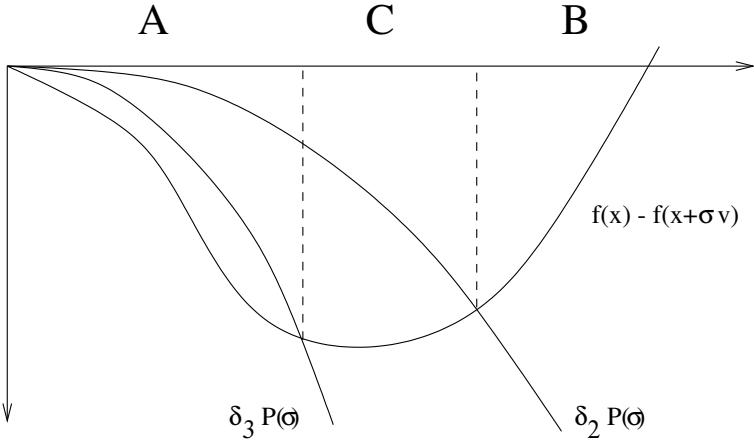

$$\sigma_{j+1} = \sigma_j + \frac{1}{2} |\sigma_{j-1} - \sigma_j|$$

else set

$$\sigma_{j+1} = \sigma_j - \frac{1}{2} |\sigma_{j-1} - \sigma_j|.$$

$j = j + 1$ and continue with **Step AB1**. ■

Note that (LSA2) distinguishes the cases A,B and C. In case of A the initial steplength ist too short, in case of B it is too long. Only in case of C the initial steplength is taken. The algorithm modifies σ_j in such a way that (12) holds. Figure 1 illustrates the situation.

Figure 1 : The decrease in f and control functions $\delta_2 P, \delta_3 P$

From (LSA1) we obtain a steplength satisfying the principle of sufficient decrease (9) (see [OR70]) in a finite number of steps. (LSA2) is also a finite algorithm, if the level set $\mathcal{L}_f(f(x^0))$ is compact.

2.2 Convergence analysis

The theoretical results presented here are based on [Hei85] and [OR70]. The basis of the convergence theory are two results on the linesearch algorithms. Using these we prove some lemmas on the directions d, r, z and finally the convergence of algorithm (UCA).

Definition 2.1 A function $\Phi : \mathbb{R}_{0+} \rightarrow \mathbb{R}_{0+}$ is said to be a *F-function (forcing function)*, if for each sequence $(\alpha_i)_{i \rightarrow \infty}$ with $\alpha_i \geq 0$ for all $i = 1, 2, \dots$ the conclusion

$$\lim_{i \rightarrow \infty} \Phi(\alpha_i) = 0 \quad \Rightarrow \quad \lim_{i \rightarrow \infty} \alpha_i = 0. \quad (13)$$

holds. ■

Lemma 2.1 Let $f \in C^1(\mathcal{D})$, \mathcal{D} open, convex and nonempty, $x^0 \in \mathcal{D}$ and $\mathcal{L}_f(f(x^0))$ compact and Φ_1, Φ_2 are F-functions. If the sequences $(x^k)_{k \rightarrow \infty}$, $(d^k)_{k \rightarrow \infty}$ and $(\sigma_k)_{k \rightarrow \infty}$ satisfy

$$\nabla^T f(x^k) d^k \leq 0, \quad (14)$$

$$\sigma_k \text{ from (LSA1) with the initial step } (\sigma_k)_0, \quad (15)$$

$$\|d^k\| (\sigma_k)_0 \geq \Phi_1 \left(\frac{|\nabla^T f(x^k) d^k|}{\|d^k\|} \right), \quad (16)$$

and

$$f(x^{k+1}) \leq f(x^k + \sigma_k d^k) \quad (17)$$

then

$$\lim_{k \rightarrow \infty} \frac{\nabla^T f(x^k) d^k}{\|d^k\|} = 0. \quad (18)$$

If moreover

$$\frac{|\nabla^T f(x^k) d^k|}{\|d^k\|} \geq \Phi_2(\|d^k\|(\sigma_k)_0) \quad (19)$$

then

$$\lim_{k \rightarrow \infty} \|d^k\| \sigma_k = 0. \quad (20)$$

Proof: The proof of statement (18) is as in Theorem 14.2.25 from [OR70] and (20) follows from (18) by (13). ■

A related lemma can be proven for (LSA2).

Lemma 2.2 Let $f \in C^2(\mathcal{D})$, \mathcal{D} open, convex and nonempty, $x^0 \in \mathcal{D}$ and $\mathcal{L}_f(f(x^0))$ compact. If the sequences $(x^k)_{k \rightarrow \infty}$, $(\tilde{v}^k)_{k \rightarrow \infty}$ and $(\sigma_k)_{k \rightarrow \infty}$ with

$$\begin{aligned} v^k &= \frac{\tilde{v}^k}{\|\tilde{v}^k\|}, & \sigma_k > 0 & \text{from (LSA2) if } \|\tilde{v}^k\| > 0 \\ v^k &= 0, & \sigma_k = 0 & \text{if } \|\tilde{v}^k\| = 0 \end{aligned} \quad (21)$$

are generated as above, and

$$f(x^{k+1}) \leq f(x^k + \sigma_k v^k) \quad (22)$$

then

$$\lim_{k \rightarrow \infty} \sigma_k = 0, \quad (23)$$

$$\lim_{k \rightarrow \infty} \nabla^T f(x^k) v^k = 0 \quad (24)$$

and

$$\lim_{k \rightarrow \infty} (v^k)^T \nabla^2 f(x^k) v^k = 0. \quad (25)$$

Proof: Since $f \in C^2(\mathcal{D})$ and $\mathcal{L}_f(f(x^0))$ is compact, there exists $\mu > 0$ such that

$$f(x) - f(x + \sigma v) \geq -\sigma \nabla^T f(x)v - \frac{1}{2}\sigma^2 v^T \nabla^2 f(x)v - \mu\sigma^3$$

for all x, σ and v with x and $x + \sigma v$ in $\mathcal{L}_f(f(x^0))$. Note that $x^k + \sigma_k v^k \in \mathcal{L}_f(f(x^0))$ by construction and so with (10) we have

$$f(x^k) - f(x^k + \sigma_k v^k) \geq \sigma_k |\Phi'_{v^k}(0)| + \frac{1}{2}(\sigma_k)^2 |\Phi''_{v^k}(0)| - \mu(\sigma_k)^3.$$

From the second inequality of (12) we obtain

$$-\sigma_k(1 - \delta_3)|\Phi'_{v^k}(0)| - \frac{1}{2}(1 - \delta_3)(\sigma_k)^2 |\Phi''_{v^k}(0)| + (\mu - \delta_3\zeta)(\sigma_k)^3 \geq 0$$

and together with (21)

$$\sigma_k \geq \frac{\omega}{2} |\Phi''_{v^k}(0)| + \sqrt{\frac{\omega^2}{4} |\Phi''_{v^k}(0)| + 2\omega |\Phi'_{v^k}(0)|} > 0, \quad (26)$$

whenever $\|v^k\| > 0$, and $\sigma_k = 0$ otherwise. Here $\omega = \frac{2(1-\delta_3)}{\mu-\delta_3\zeta}$.

Because f is bounded from below on $\mathcal{L}_f(f(x^0))$ (12) implies

$$\lim_{k \rightarrow \infty} f(x^k) - f(x^k + \sigma_k v^k) = 0.$$

Together with (10) and (21) we have

$$\lim_{k \rightarrow \infty} \sigma_k = 0$$

and finally with (26) we obtain

$$\lim_{k \rightarrow \infty} \nabla^T f(x^k) v^k = 0 \quad \text{and} \quad \lim_{k \rightarrow \infty} (v^k)^T \nabla^2 f(x^k) v^k = 0.$$

■

To state some results concerning the directions of descent we need some information about the second directional derivative in the direction of d, r or z and the ritzvalues computed by the Lanczos algorithm.

Lemma 2.3 *Let $A \in \mathbb{R}^{n \times n}$ be symmetric. Then the truncated Lanczos decomposition (ν steps) of A is given by*

$$AQ = QT + \beta q_{\nu+1} e_{\nu}^T \quad \text{and} \quad Q^T Q = I, \quad (27)$$

where $Q \in \mathbb{R}^{n \times \nu}$ and $T, I \in \mathbb{R}^{\nu \times \nu}$. Let

$$T = VDV^T \quad \text{and} \quad V^T V = I \quad (28)$$

be the spectral decomposition of the tridiagonal matrix T . Let $\mathcal{I} \subset \{1, \dots, \nu\}$, $S_{\mathcal{I}} \stackrel{\text{def}}{=} QV_{\mathcal{I}}$, and $d \stackrel{\text{def}}{=} S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c$ for an arbitrary $c \in \mathbb{R}^n$ and an arbitrary diagonal matrix $\Delta_{\mathcal{I}} \stackrel{\text{def}}{=} \text{diag}(\tilde{\delta}_i)_{i \in \mathcal{I}}$ with positive elements $\tilde{\delta}_i > 0$. Then

$$\begin{aligned} D_{\mathcal{I}} > 0 &\Rightarrow d^T Ad > 0 \\ D_{\mathcal{I}} \geq 0 &\Rightarrow d^T Ad \geq 0 \\ D_{\mathcal{I}} < 0 &\Rightarrow d^T Ad < 0. \end{aligned} \quad (29)$$

Proof: From (28) follows

$$TV_{\mathcal{I}} = (TV)_{\mathcal{I}} = (VD)_{\mathcal{I}} = V_{\mathcal{I}} D_{\mathcal{I}}.$$

Hence with (27)

$$\begin{aligned} AS_{\mathcal{I}} = AQV_{\mathcal{I}} &= QTV_{\mathcal{I}} + \beta q_{\nu+1} e_{\nu}^T V_{\mathcal{I}} \\ &= QV_{\mathcal{I}} D_{\mathcal{I}} + \beta q_{\nu+1} e_{\nu}^T V_{\mathcal{I}} \\ &= S_{\mathcal{I}} D_{\mathcal{I}} + \beta q_{\nu+1} e_{\nu}^T V_{\mathcal{I}}. \end{aligned} \quad (30)$$

Using (30) $d^T Ad$ can be written

$$\begin{aligned}
 d^T Ad &= c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T A S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c \\
 &= c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T (S_{\mathcal{I}} D_{\mathcal{I}} + \beta q_{\nu+1} e_{\nu}^T V_{\mathcal{I}}) \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c \\
 &= c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} \underbrace{S_{\mathcal{I}}^T S_{\mathcal{I}}}_{=I} D_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c + \beta c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T q_{\nu+1} e_{\nu}^T V_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c \quad (31) \\
 &= c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} D_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c + \beta c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} V_{\mathcal{I}}^T \underbrace{Q^T q_{\nu+1}}_{=0} e_{\nu}^T V_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c \\
 &= c^T S_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} D_{\mathcal{I}} \Delta_{\mathcal{I}}^{-1} S_{\mathcal{I}}^T c.
 \end{aligned}$$

Since $\tilde{\delta}_i > 0$ for all $i \in \mathcal{I}$ (31) completes the proof. \blacksquare

These lemmata are very useful in order to analyze the sequence (x^k, d^k, r^k, z^k) . First we take a look at the directions d^k .

Lemma 2.4 *Let $f \in C^2(\mathcal{D})$, \mathcal{D} open, convex and nonempty, $x^0 \in \mathcal{D}$, $\mathcal{L}_f(f(x^0))$ compact, and the sequences $(x^k)_{k \rightarrow \infty}$, $(d^k)_{k \rightarrow \infty}$ and $((\sigma_d)_k)_{k \rightarrow \infty}$ be generated by the algorithm (UCA). Then*

$$\lim_{k \rightarrow \infty} \frac{\nabla^T f(x^k) d^k}{\|d^k\|} = 0 \quad (32)$$

and

$$\lim_{k \rightarrow \infty} \|d^k\| (\sigma_d)_k = 0. \quad (33)$$

Proof: From lemma 2.3 we know that $(d^k)^T \nabla^2 f(x^k) d^k \geq 0$. Hence $(\sigma_d)_k$ will always be computed by (LSA1). Therefore we verify (32) and (33) using lemma 2.1.

To make use of lemma 2.1 we have to show that the assumptions (14) to (17) and (19) hold. Since (14), (15) and (17) are satisfied by construction, only (16) and (19) have to be shown.

Because $\mathcal{L}_f(f(x^0))$ is compact and $x^k \in \mathcal{L}_f(f(x^0))$ for all k the maximum eigenvalue of the Hessian $\nabla^2 f(x^k)$ is bounded from above by some $\bar{\lambda} > 0$. Moreover the minimum diagonal element of the matrix \bar{D}_ν^k is greater than or equal to $\rho > 0$. Using these two parameters we can estimate

$$\begin{aligned}
 \frac{1}{\bar{\lambda} + \rho} (-\nabla^T f(x^k) d^k) &= \sum_{i \in \mathcal{N}_{+0}} \frac{(\nabla^T f(x^k) s_i^k)^2}{(\max(\lambda_i^k, \rho)(\bar{\lambda} + \rho))} \\
 &\leq \underbrace{\sum_{i \in \mathcal{N}_{+0}} \frac{(\nabla^T f(x^k) s_i^k)^2}{(\max(\lambda_i^k, \rho))^2}}_{\|d^k\|^2} \leq \frac{1}{\rho} (-\nabla^T f(x^k) d^k)
 \end{aligned}$$

and

$$\rho \leq \frac{|\nabla^T f(x^k) d^k|}{\|d^k\|^2} \leq \bar{\lambda} + \rho. \quad (34)$$

There are two possible initial steps for (LSA1):

i) Let $(\sigma_d)_0 = 1$. Then

$$\frac{|\nabla^T f(x^k)d^k|}{\|d^k\|} = \frac{|\nabla^T f(x^k)d^k|}{\|d^k\|^2} \|d^k\| (\sigma_d)_0$$

and with (34)

$$\rho \|d^k\| (\sigma_d)_0 \leq \frac{|\nabla^T f(x^k)d^k|}{\|d^k\|} \leq (\bar{\lambda} + \rho) \|d^k\| (\sigma_d)_0. \quad (35)$$

ii) Since $(\sigma_d)_0 = -\frac{\Phi'_d(0)}{\Phi''_d(0)} < 1$

$$\frac{|\nabla^T f(x^k)d^k|}{\|d^k\|} \geq \frac{|\nabla^T f(x^k)d^k|}{\|d^k\|^2} \|d^k\| (\sigma_d)_0.$$

Otherwise we have

$$(\sigma_d)_0 \|d^k\| = \frac{|\nabla^T f(x^k)d^k|}{(d^k)^T \nabla^2 f(x^k) d^k} \|d^k\| = \frac{|\nabla^T f(x^k)d^k|}{\|d^k\|} \frac{\|d^k\|^2}{(d^k)^T \nabla^2 f(x^k) d^k}.$$

Hence

$$\begin{aligned} \frac{|\nabla^T f(x^k)d^k|}{\|d^k\|} &= (\sigma_d)_0 \|d^k\| \frac{(d^k)^T \nabla^2 f(x^k) d^k}{\|d^k\|^2} \\ &\leq \bar{\lambda} (\sigma_d)_0 \|d^k\| \leq (\bar{\lambda} + \rho) (\sigma_d)_0 \|d^k\|. \end{aligned} \quad (36)$$

Using (34) and (36) we obtain the same estimation as in case i)

$$\rho \|d^k\| (\sigma_d)_0 \leq \frac{|\nabla^T f(x^k)d^k|}{\|d^k\|} \leq (\bar{\lambda} + \rho) \|d^k\| (\sigma_d)_0. \quad (37)$$

Since $\Phi_1(\alpha) = \frac{1}{\bar{\lambda} + \rho} \alpha$ and $\Phi_2(\alpha) = \rho \alpha$ are F-functions (16) and (19) are satisfied. ■

Lemma 2.5 *Let $f \in C^2(\mathcal{D})$, \mathcal{D} open, convex and nonempty, $x^0 \in \mathcal{D}$, $\mathcal{L}_f(f(x^0))$ compact, and the sequences $(x^k)_{k \rightarrow \infty}$, $(x_d^k)_{k \rightarrow \infty}$, $(r^k)_{k \rightarrow \infty}$ and $((\sigma_r)_k)_{k \rightarrow \infty}$ be generated by the algorithm (UCA). If*

$$\lim_{k \rightarrow \infty} (x_d^k - x^k) = 0 \quad (38)$$

then

$$\lim_{k \rightarrow \infty} \frac{\nabla^T f(x_d^k) r^k}{\|r^k\|} = \lim_{k \rightarrow \infty} \frac{\nabla^T f(x^k) r^k}{\|r^k\|} = 0, \quad (39)$$

$$\lim_{k \rightarrow \infty} \|r^k\| (\sigma_r)_k = 0 \quad (40)$$

and

$$\lim_{k \rightarrow \infty} \frac{(r^k)^T \nabla^2 f(x_d^k) r^k}{\|r^k\|^2} = 0. \quad (41)$$

Proof: Since it is possible that $\Phi_r''(0) = r^T \nabla^2 f(x_d^k) r^k \geq 0$ we have to distinguish the subsequences $(x^k)_{k \in K_i}$, $(x_d^k)_{k \in K_i}$, $(r^k)_{k \in K_i}$, $((\sigma_r)_k)_{k \in K_i}$ with $i = 1, 2$ and $K_1 \stackrel{\text{def}}{=} \{k : \Phi_r''(0) \geq 0\}$, $K_2 \stackrel{\text{def}}{=} \{0, 1, 2, \dots\} \setminus K_1$. If $k \in K_1$ then $(\sigma_r)_k$ is computed by (LSA1) and by (LSA2) in case of $k \in K_2$.

Case 1 : (LSA1)

Like in the proof of lemma 2.4 only assumptions (16) and (19) have to be shown in order to make use of lemma 2.1. There are two possible initial steps:

i) Let $(\sigma_r)_0 = 1$. Then

$$\begin{aligned} \frac{|\nabla^T f(x^k) r^k|}{\|r^k\|} &= \frac{|\nabla^T f(x^k) (S_\nu^k)_{N_-} (S_\nu^k)_{N_-}^T \nabla f(x^k)|}{\|r^k\|} \\ &= \frac{\|(S_\nu^k)_{N_-}^T \nabla f(x^k)\|^2}{\|r^k\|} = \frac{\|r^k\|^2}{\|r^k\|} = \|r^k\|, \end{aligned}$$

because the columns of S_ν^k are orthonormal. Hence we obtain

$$\frac{|\nabla^T f(x^k) r^k|}{\|r^k\|} = \|r^k\| (\sigma_r)_0. \quad (42)$$

ii) If $(\sigma_r)_0 = -\frac{\Phi_r'(0)}{\Phi_r''(0)} < 1$, then from (42) there follows

$$\frac{|\nabla^T f(x^k) r^k|}{\|r^k\|} = \|r^k\| > \|r^k\| (\sigma_r)_0. \quad (43)$$

On the other hand

$$\|r^k\| (\sigma_r)_0 = \frac{|\nabla^T f(x_d^k) r^k|}{(r^k)^T \nabla^2 f(x_d^k) r^k} \|r^k\| = \frac{|\nabla^T f(x_d^k) r^k|}{\|r^k\|} \frac{\|r^k\|^2}{(r^k)^T \nabla^2 f(x_d^k) r^k}$$

and with $\bar{\lambda} > 1$ as an upper bound on the eigenvalues of $\nabla^2 f(x)$ on the compact set $\mathcal{L}_f(f(x^0))$ we have

$$\bar{\lambda} \|r^k\| (\sigma_r)_0 \geq \frac{|\nabla^T f(x_d^k) r^k|}{\|r^k\|}. \quad (44)$$

Due to the continuity of the directional derivative and (38) there exists an index $k_1 \in K_1$ such that for all $k \geq k_1$ the estimates (42), (43) and (44) can be combined to

$$\|r^k\| (\sigma_r)_0 \leq \frac{|\nabla^T f(x_d^k) r^k|}{\|r^k\|} \leq \bar{\lambda} \|r^k\| (\sigma_r)_0. \quad (45)$$

Note that $\bar{\lambda}$ was chosen greater than 1. With (45) the assumptions (16) and (19) are satisfied and hence (39) and (40) hold.

To verify (41) we make use of lemma 2.3. With $\tilde{\delta}_i = 1$ for $i \in \mathcal{I}$ and $\mathcal{I} = \mathcal{N}_-$ we know that $(r^k)^T \nabla^2 f(x^k) r^k < 0$. Hence, for all $k \in K_1$

$$\frac{(r^k)^T \nabla^2 f(x^k) r^k}{\|r^k\|^2} \leq 0 \leq \frac{(r^k)^T \nabla^2 f(x_d^k) r^k}{\|r^k\|^2}$$

and from (38)

$$\lim_{k \in K_1} \frac{(r^k)^T \nabla^2 f(x_d^k) r^k}{\|r^k\|^2} = 0.$$

follows.

Case 2 : (LSA2)

This case is much easier to prove. For $k \in K_2$ the steplength $(\sigma_r)_0$ will be computed by (LSA2). The assumptions of lemma 2.2 are satisfied by construction and together with (38) and $f \in C^2(\mathcal{D})$ we obtain (39) to (41) for $k \in K_2$. ■

Lemma 2.6 *Let $f \in C^2(\mathcal{D})$, \mathcal{D} open, convex and nonempty, $x^0 \in \mathcal{D}$, $\mathcal{L}_f(f(x^0))$ compact, and the sequences $(x^k)_{k \rightarrow \infty}$, $(x_r^k)_{k \rightarrow \infty}$, $(z^k)_{k \rightarrow \infty}$ and $((\sigma_z)_k)_{k \rightarrow \infty}$ be generated by the algorithm (UCA). If*

$$\lim_{k \rightarrow \infty} (x_r^k - x^k) = 0 \quad (46)$$

then

$$\lim_{k \rightarrow \infty} \frac{\nabla^T f(x_r^k) z^k}{\|z^k\|} = \lim_{k \rightarrow \infty} \frac{\nabla^T f(x^k) z^k}{\|z^k\|} = 0, \quad (47)$$

$$\lim_{k \rightarrow \infty} \|z^k\| (\sigma_z)_k = 0 \quad (48)$$

and

$$\lim_{k \rightarrow \infty} \frac{(z^k)^T \nabla^2 f(x_r^k) z^k}{\|z^k\|^2} = 0. \quad (49)$$

Proof: The proof of this lemma is analogous to the proof of lemma 2.5. One only has to substitute x_d, r, σ_r, Φ_r by x_r, z, σ_z, Φ_z . ■

Finally we prove the convergence of the algorithm using the hitherto given lemmata.

Theorem 2.1 *Let $f \in C^3(\mathcal{D})$, \mathcal{D} open, convex and nonempty. Let $x^0 \in \mathcal{D}$ and assume $\mathcal{L}_f(f(x^0))$ being compact. Let the sequence $(x^k)_{k \rightarrow \infty}$ be generated by the algorithm (UCA). If we assume that the minimum eigenvalue of the Hessian $\nabla^2 f(x^k)$ can be approximated sufficiently close by the Lanczos algorithm for all k , then $(x^k)_{k \rightarrow \infty}$ has at least one accumulation point and each accumulation point x^* satisfies*

$$\nabla f(x^*) = 0 \quad (50)$$

and

$$\nabla^2 f(x^*) \text{ positive semidefinite.} \quad (51)$$

Proof: Since $\mathcal{L}_f(f(x^0))$ is compact and $(x^k)_{k \rightarrow \infty} \subset \mathcal{L}_f(f(x^0))$ an accumulation point x^* exists. Let $K \subset \{0, 1, 2, \dots\}$ be the index set of the subsequence $(x^k)_{k \in K}$ converging to x^* . Then from lemma 2.4 - 2.6 we know

$$\lim_{k \in K} \nabla^T f(x^k) d^k = \lim_{k \in K} \nabla^T f(x^k) r^k = \lim_{k \in K} \nabla^T f(x^k) z^k = 0 \quad (52)$$

and

$$\lim_{k \in K} (x^k - x_d^k) = \lim_{k \in K} (x^k - x_r^k) = \lim_{k \in K} (x_d^k - x_r^k) = 0. \quad (53)$$

To estimate $\|\nabla f(x^*)\|$ from above we first have a look at

$$\|(S_\nu^k)^T \nabla f(x^k)\|^2 = \underbrace{\left((s_1^k)^T \nabla f(x^k) \right)^2}_{(1)} + \underbrace{\left\| (S_\nu^k)_{\mathcal{N}_-}^T \nabla f(x^k) \right\|^2}_{(2)} + \underbrace{\left\| (S_\nu^k)_{\mathcal{N}_{+0}}^T \nabla f(x^k) \right\|^2}_{(3)}. \quad (54)$$

If any of the index sets \mathcal{N}_- or \mathcal{N}_{+0} are empty the corresponding summand can be omitted.

$$(1): ((s_1^k)^T \nabla f(x^k))^2 = |(z^k)^T \nabla f(x^k)|^2.$$

$$(2): \left\| (S_\nu^k)_{\mathcal{N}_-}^T \nabla f(x^k) \right\|^2 = |\nabla^T f(x^k) (S_\nu^k)_{\mathcal{N}_-} (S_\nu^k)_{\mathcal{N}_-}^T \nabla f(x^k)|^2 = |(r^k)^T \nabla f(x^k)|^2$$

$$(3): \frac{1}{\lambda + \rho} \left\| (S_\nu^k)_{\mathcal{N}_{+0}}^T \nabla f(x^k) \right\|^2 \leq |\nabla^T f(x^k) (S_\nu^k)_{\mathcal{N}_{+0}} (S_\nu^k)_{\mathcal{N}_{+0}}^T \nabla f(x^k)|^2 = |(d^k)^T \nabla f(x^k)|^2$$

Using this (54) becomes

$$\|(S_\nu^k)^T \nabla f(x^k)\|^2 \leq (\bar{\lambda} + \rho) |(d^k)^T \nabla f(x^k)|^2 + |(r^k)^T \nabla f(x^k)|^2 + |(z^k)^T \nabla f(x^k)|^2.$$

Hence

$$\lim_{k \in K} \|(S_\nu^k)^T \nabla f(x^k)\| = 0. \quad (55)$$

By definition $S_\nu^k = Q_\nu^k V_\nu^k$. Since V_ν^k is a unitary matrix we obtain

$$\|(S_\nu^k)^T \nabla f(x^k)\| = \|(V_\nu^k)^T (Q_\nu^k)^T \nabla f(x^k)\| = \|(Q_\nu^k)^T \nabla f(x^k)\|. \quad (56)$$

The first column of the matrix Q_ν^k is the normalized initial vector of the Lanczos iteration $-\nabla f(x^k)$ (see **Step 1** of (UCA)). Therefore

$$\|(Q_\nu^k)^T \nabla f(x^k)\| = \sqrt{\left(\frac{\nabla^T f(x^k) \nabla f(x^k)}{\|\nabla f(x^k)\|} \right)^2 + \sum_{i=2}^{\nu} \left((q_i^k)^T \nabla f(x^k) \right)^2}$$

holds. Hence from (55) and (56) follows

$$\lim_{k \in K} \|\nabla f(x^k)\| = 0.$$

To verify (51) only the directions z^k are needed, as we have assumed that λ_1^k from the truncated Lanczos decomposition in **Step 1** or **Step 5** of (UCA) approximates the minimum eigenvalue of the Hessian accurately. From (49) and (46) we get (51) because

$$(z^k)^T \nabla^2 f(x^k) z^k = \min\{\lambda_{\min}(\nabla^2 f(x^k)), 0\}.$$

■

Remark 2.1 To proof the previous theorem we needed an assumption on the convergence of the minimum ritzvalue λ_1^k against the minimum eigenvalue of the Hessian $\nabla^2 f(x^k)$. A very interesting result is given in [GL89]. Theorem 9.2.2 implies that λ_1^k is a good approximation to the minimum eigenvalue whenever the first Lanczos vector q_1^k of the Lanczos algorithm and the normalized eigenvector z_1 to the minimum eigenvalue are not orthogonal. The approximation is the better, the nearer $(z_1)^T q_1^k$ is by 1. Therefore we use a random start vector in **Step 5** of (UCA).

Nevertheless we cannot prevent a gap between the minimum eigenvalue of the Hessian of the objective function ($\lambda_{\min}(\nabla^2 f(x))$) and the minimum ritzvalue λ_1 , because we truncate the computation of the Lanczos decomposition after at last ν steps. But usually λ_1 is a good approximation for $\lambda_{\min}(\nabla^2 f(x))$ and so an existing negative curvature direction can be identified in most cases. ■

3 Bound constrained problems

The generalization from the unconstrained case to the bound constrained one is not difficult. To specify the second order necessary condition we need the projection of the gradient on the box defined by Ω_B . We define it componentwise by

$$(P(\nabla f(x)))_i \stackrel{\text{def}}{=} \begin{cases} \min\{0, (\nabla f(x))_i\} & \text{if } x_i = l_i \\ (\nabla f(x))_i & \text{if } l_i < x_i < u_i \\ \max\{0, (\nabla f(x))_i\} & \text{if } x_i = u_i. \end{cases} \quad (57)$$

The first order necessary condition is fulfilled in a feasible point x^* if

$$P(\nabla f(x^*)) = 0. \quad (58)$$

Such a point is called a stationary point. Moreover, if the reduced Hessian

$$I_{\mathcal{F}(x^*)}^T \nabla^2 f(x^*) I_{\mathcal{F}(x^*)} \quad (59)$$

is positive semidefinite, then the second order necessary condition holds in x^* . The index set \mathcal{F} is the set of the free variables

$$\mathcal{F}(x^*) \stackrel{\text{def}}{=} \{i \in \{1, \dots, n\} : l_i < x_i < u_i\}.$$

The complementary set of $\mathcal{F}(x^*)$

$$\mathcal{A}(x^*) \stackrel{\text{def}}{=} \{i \in \{1, \dots, n\} : x_i = l_i \text{ or } x_i = u_i\}.$$

is the so-called active set. Note, that if the strict complementarity condition

$$(\nabla f(x))_i < 0 \quad \text{if } x_i = l_i \quad \text{and} \quad (\nabla f(x))_i > 0 \quad \text{if } x_i = u_i \quad (60)$$

is fulfilled in a point x^* satisfying (58), then the positive definiteness of (59) is sufficient for x^* being a strict local minimizer.

The following algorithm based upon (UCA) can only find a point satisfying the second order necessary condition. To specify the algorithm (BCA) the projection on the feasible region

$$(P_\Omega(x))_i \stackrel{\text{def}}{=} \begin{cases} l_i & \text{if } x_i \leq l_i \\ u_i & \text{if } x_i \geq u_i \\ x_i & \text{otherwise.} \end{cases} \quad (61)$$

is needed.

Instead of the projected gradient (57) we make use of the projection on the box (61) to define an equivalent condition to (58). It is easy to see that

$$x^* - P_\Omega(x^* - \nabla f(x^*)) = 0 \Leftrightarrow P(\nabla f(x^*)) = 0. \quad (62)$$

To verify the condition $\|x^* - P_\Omega(x^* - \nabla f(x^*))\| = 0$ has some numerical advantages, because $(x - P_\Omega(x - \nabla f(x)))_i$ is continuous in l_i and u_i .

To describe an algorithm for solving (UCP) we need the following index sets

Definition 3.1 In a given point $x \in \Omega_B$

$$\tilde{\mathcal{F}}(x) \stackrel{\text{def}}{=} \left\{ i \in \{1, \dots, n\} : \begin{array}{ll} l_i < x_i < u_i & \text{or} \\ x_i = l_i \text{ and } (\nabla f(x))_i < 0 & \text{or} \\ x_i = u_i \text{ and } (\nabla f(x))_i > 0 \end{array} \right\} \quad (63)$$

is the augmented set of free variables and its complement

$$\mathcal{B}(x) \stackrel{\text{def}}{=} \left\{ i \in \{1, \dots, n\} : \begin{array}{ll} x_i = l_i \text{ and } (\nabla f(x))_i \geq 0 & \text{or} \\ x_i = u_i \text{ and } (\nabla f(x))_i \leq 0 \end{array} \right\} \quad (64)$$

is the so-called binding set. ■

Moreover, to define a quasi unconstrained optimization problem on a face of the box we need a reduced function.

Definition 3.2 Let $x \in \Omega_B$ be given and let $\mathcal{J}(x)$ be an index set associated with x , then we define the $\mathcal{J}(x)$ -reduced function $f_{\mathcal{J}(x)}(y) : \mathbb{R}^{|\mathcal{J}(x)|} \rightarrow \mathbb{R}$ by

$$f_{\mathcal{J}(x)}(y) \stackrel{\text{def}}{=} f(x_{\mathcal{J}(x)}(y)) \quad \text{with} \quad x_{\mathcal{J}(x)}(y) \stackrel{\text{def}}{=} \begin{cases} (I_{\mathcal{J}(x)} y)_i & \text{if } i \in \mathcal{J}(x) \\ x_i & \text{otherwise} \end{cases}$$

Remark 3.1 Note that the derivatives of the reduced function are given by

$$\nabla f_{\mathcal{J}(x)}(y) = I_{\mathcal{J}(x)}^T \nabla f(x_{\mathcal{J}(x)}(y)) \quad \text{and} \quad \nabla^2 f_{\mathcal{J}(x)}(y) = I_{\mathcal{J}(x)}^T \nabla^2 f(x_{\mathcal{J}(x)}(y)) I_{\mathcal{J}(x)}. \quad ■$$

3.1 Outline of the algorithm

Algorithm 3.1 (BCA)

Given the starting point $x^0 \in \Omega_B$ and parameters $0 < \epsilon \ll 1$, $0 < \eta_1, \eta_2 < 1$ and $2 \leq l \in \mathbb{N}$. Set $k = 0$ and proceed

Step 0 If

$$\|x^k - P_\Omega(x^k - \nabla f(x^k))\| \leq \epsilon \quad (65)$$

continue with **Step 11**.

Step 1 Determine the binding set $\mathcal{B}(x^k)$ and the active set $\mathcal{A}(x^k)$ in the current iterate x^k . If

$$\mathcal{A}(x^k) = \mathcal{B}(x^k)$$

then goto **Step 5**. Otherwise set $k_g = k$.

Step 2 Compute a steplength σ_g along the polygonal search path $P_\Omega(x^k - t\nabla f(x^k))$ using the linesearch algorithms (LSA1) and (LSA2).

Let $\Phi(t, \nabla f(x^k)) \stackrel{\text{def}}{=} f(P_\Omega(x^k - t\nabla f(x^k)))$ and compute

$$\Phi'_{\nabla f(x^k)}(0) = -\nabla^T f(x^k)P(\nabla f(x^k)) = -\|P(\nabla f(x^k))\|^2 \quad (66)$$

and

$$\Phi''_{\nabla f(x^k)}(0) = P(\nabla f(x^k))^T \nabla^2 f(x^k)P(\nabla f(x^k)). \quad (67)$$

To get σ_g use the following scheme

(i) If $\Phi''_{\nabla f(x^k)}(0) > 0$ then use (LSA1) with

$$(\sigma_g)_0 = \min \left\{ 1, -\frac{\Phi'_{\nabla f(x^k)}(0)}{\Phi''_{\nabla f(x^k)}(0)} \right\}.$$

(ii) If $\Phi''_{\nabla f(x^k)}(0) = 0$ then use (LSA1) with

$$(\sigma_g)_0 = 1.$$

(iii) If $\Phi''_{\nabla f(x^k)}(0) < 0$ then use (LSA2) with

$$(\sigma_g)_0 = \begin{cases} \|x^k - x^{k-1}\| & \text{if } k > 0 \\ \|P(\nabla f(x^k))\| & \text{if } k = 0 \end{cases}$$

Set

$$x^{k+1} \stackrel{\text{def}}{=} P_\Omega(x^k - \sigma_g \nabla f(x^k)).$$

Step 3 If

$$\|x^{k+1} - P_\Omega(x^{k+1} - \nabla f(x^{k+1}))\| \leq \epsilon \quad (68)$$

continue with **Step 11**.

Step 4 If

$$\mathcal{A}(x^{k+1}) = \mathcal{A}(x^k) = \cdots = \mathcal{A}(x^{k+1-l})$$

or

$$f(x^k) - f(x^{k+1}) \leq \eta_1 \max_{k_g \leq j < k} \{f(x^j) - f(x^{j+1})\}$$

then set $k = k + 1$ and continue with **Step 5**. Else set $k = k + 1$ and goto **Step 1**.

Step 5 Set $\mathcal{F} = \mathcal{F}(x^k)$ and define the \mathcal{F} -reduced function $f_{\mathcal{F}}(y)$. Set $i = 0$ and $y^0 = I_{\mathcal{F}}^T x^k$.

Step 6 Use **Step 1** of (UCA) with $f_{\mathcal{F}}$ replacing f .

Step 7 Use **Step 2** of (UCA) with $f_{\mathcal{F}}$ replacing f .

Step 8 Use **Step 3** of (UCA) with $f_{\mathcal{F}}$ replacing f and obtain y^{i+1} .

Step 9 Set

$$x^{k+1} = P_{\Omega}(x_{\mathcal{F}}(y^{i+1})).$$

If

$$\|x^{k+1} - P_{\Omega}(x^{k+1} - \nabla f(x^{k+1}))\| \leq \epsilon \quad (69)$$

continue with **Step 11**.

Step 10 If

$$\mathcal{A}(x^{k+1}) \neq \mathcal{A}(x^k)$$

or

$$f_{\mathcal{F}}(y^i) - f_{\mathcal{F}}(y^{i+1}) \leq \eta_2 \max_{0 \leq j < i} \{f_{\mathcal{F}}(y^j) - f_{\mathcal{F}}(y^{j+1})\}$$

or

$$\|\nabla f_{\mathcal{F}}(y^{i+1})\| \leq \epsilon$$

then set $k = k + 1$ and continue with **Step 1**. Otherwise set $k = k + 1$, $i = i + 1$ and proceed with **Step 6**.

Step 11 As in the unconstrained case compute the truncated Lanczos decomposition for the $\tilde{\mathcal{F}}(x^k)$ -reduced function $f_{\tilde{\mathcal{F}}(x^k)}$ to determine the index sets $\mathcal{N}_- = \{i : \lambda_i^k < 0\}$ and $\mathcal{N}_{+0} = \{i : \lambda_i^k \geq 0\}$ of negative and non-negative ritzvalues of the reduced Hessian.

If $|\mathcal{N}_-| = 0$ stop.

If $|\mathcal{N}_-| \neq 0$ then continue with **Step 7** replacing $f_{\mathcal{F}}$ by $f_{\tilde{\mathcal{F}}(x^k)}$. ■

Remark 3.2 The algorithm (BCA) is a combination of the gradient projection method and the unconstrained minimizer (UCA). Thereby the gradient projection steps have the job to find the correct set of active variables by multiple activation/inactivation and (UCA) explores a face of the box defined by Ω_B . ■

Remark 3.3 Note that the algorithm (BCA) only stops in **Step 11** which only can be reached if a stationary point was identified by (65), (68) or (69). The replacement of $f_{\mathcal{F}}$ by $f_{\tilde{\mathcal{F}}(x^k)}$ is a special feature to determine directions of negative curvature in a stationary point not satisfying the strict complementarity condition (60). For the convergence result presented below it is irrelevant, since we assume (60) hold in x^* . This guarantees identification of the correct active set in a finite number of steps, and $\mathcal{F}(x^*) = \tilde{\mathcal{F}}(x^*)$. ■

Remark 3.4 The first and second directional derivative of f in the direction of the projected gradient defined by (66) and (67) exists, because

$$P_{\Omega}(x^k - t\nabla f(x^k)) = x^k - tP(\nabla f(x^k))$$

for $0 \leq t \leq \beta_1$, where β_1 is the first breakpoint of the piecewise linear path, if $P(\nabla f(x^k)) \neq 0$. ■

3.2 Convergence analysis

The transfer of the convergence properties from theorem 2.1 to the bound constrained case follows from theorem 5.4. in [CM87]. Calamai and Moré refer to an algorithm combining the projected gradient steps with another method satisfying $x^{k+1} \in \Omega_B$, $f(x^{k+1}) \leq f(x^k)$ and $\mathcal{A}(x^{k+1}) \subset \mathcal{A}(x^k)$. Theorem 5.4. in [CM87] shows that a bounded sequence generated by this algorithm stays on the correct active set after a finite number of steps, whenever the strict complementary condition (60) holds in each stationary point.

Theorem 3.1 Let $f \in C^3(\mathcal{D})$, \mathcal{D} open, convex and nonempty, $x^0 \in \mathcal{D}$ and $\mathcal{L}_f(f(x^0)) \cap \Omega_B$ compact. Let the sequence $(x^k)_{k \rightarrow \infty}$ be generated by the algorithm (BCA). We assume that the minimum eigenvalue of the reduced Hessian can be approximated sufficiently good by the Lanczos algorithm in **Step 11**.

If the strict complementarity condition (60) is satisfied in each stationary point of (BCP), then $(x^k)_{k \rightarrow \infty}$ has at least one accumulation point and each accumulation point x^* satisfies

$$P(\nabla f(x^*)) = 0 \tag{70}$$

and

$$I_{\tilde{\mathcal{F}}(x^*)}^T \nabla^2 f(x_{\tilde{\mathcal{F}}(x^*)}(y)) I_{\tilde{\mathcal{F}}(x^*)} \quad \text{positive semidefinite.} \tag{71}$$

Proof: If we assume that (60) holds in each stationary point, then in **Step 11** $\tilde{\mathcal{F}}(x^k)$ can be replaced by $\mathcal{F}(x^k)$ and so the assumptions of theorem 5.4. from [CM87] are satisfied.

Hence, the bounded sequence $(x^k)_{k \rightarrow \infty}$ remains on one face of the box for all k sufficiently large. By construction this only happens if $\mathcal{A}(x^k) = \mathcal{B}(x^k)$ is satisfied for k sufficiently large. Hence we can use theorem 2.1 to complete the proof. ■

4 Implementation

Now we have a look at the implementation of (BCA). In the algorithms we make use of the Lanczos decomposition of the Hessian or the reduced Hessian of the objective function. Here we present two implemented features which serve to increase stability and effectiveness.

4.1 Partial reorthogonalization

The Lanczos decomposition of a symmetric matrix A in exact arithmetic can be written concisely as

$$\begin{aligned} AQ_\nu - Q_\nu T_\nu &= \beta_{\nu+1} q_{\nu+1} e_\nu^T \\ Q_\nu^T Q_\nu &= I_\nu. \end{aligned} \tag{72}$$

In practical computing the columns of Q_ν , the so-called Lanczos vectors, lose their orthogonality. As a consequence of this $Q_\nu^T Q_\nu \neq I_\nu$ even for $\nu \ll n$. But without the orthogonality lemma 2.3 does not hold and the algorithm may fail.

This problem is well known and described in detail in [Par80a]. The only way to stabilize the computation of (72) is to orthogonalize the current computed Lanczos vector relatively to the previous ones. To use all the Lanczos vectors for reorthogonalization is very expensive and not necessary. Therefore Parlett developed in [Par80a], [Par80b] or [PS79] a strategy called “Selective Orthogonalization (SO)”. The (SO) method determines exactly the ritzvectors relative to which the current Lanczos vector loses orthogonality and reorthogonalizes it.

Another way to prevent the breakdown was presented in [Sim84b] and [Sim84a]. Simons idea is to simulate the loss of orthogonality and to decide relative to which of the older Lanczos vectors a new one should be corrected. The foundation of the simulation is the following theorem proved in [Sim84a].

Lemma 4.1 *Let $\omega_{i,j} = q_i^T q_j$. Then the $\omega_{i,k}$ satisfy the recurrence*

$$\begin{aligned} \omega_{k,k} &= 1 && \text{for } k = 1, \dots, j+1, \\ \omega_{k,k-1} &= q_k^T q_{k-1} && \text{for } k = 2, \dots, j+1, \\ \beta_{j+1} \omega_{j+1,k} &= \beta_{k+1} \omega_{j,k+1} + (\alpha_k - \alpha_j) \omega_{j,k} + \beta_k \omega_{j,k-1} - \beta_j \omega_{j-1,k} \\ &\quad + q_j^T f_k - q_k^T f_j, \end{aligned} \tag{73}$$

for $1 \leq k < j$ and $\omega_{j,k+1} = \omega_{k+1,j}$, where $\omega_{k,0} \equiv 0$ and the vectors f_i account for the rounding errors in the i -th step.

Proof: The recurrence (73) follows from the three-term-recurrence of the Lanczos algorithm by adding an error vector f . For further details see [Sim84a]. ■

Introducing some reasonable estimates for the error-vectors it is possible to estimate the $\omega_{j,k}$'s by

$$\begin{aligned} \omega_{k,k} &= 1 \quad \text{for } k = 1, \dots, j+1, \\ \omega_{k,k-1} &= \phi_k \quad \text{for } k = 2, \dots, j+1, \\ \omega_{j+1,k} &= \frac{1}{\beta_{j+1}} (\beta_{k+1}\omega_{j,k+1} + (\alpha_k - \alpha_j)\omega_{j,k} + \beta_k\omega_{j,k-1} - \beta_j\omega_{j-1,k}) \\ &\quad + \theta_{j,k}, \end{aligned} \tag{74}$$

for $1 \leq k < j$ and $\omega_{j,k+1} = \omega_{k+1,j}$. For ϕ_k and $\theta_{j,k}$ Simon proposed

$$\phi_k = \epsilon_M n \frac{\beta_2}{\beta_k} \Phi,$$

where $\Phi \in (-0.3, 0.3)$ and

$$\theta_{j,k} = \epsilon_M (\beta_{k+1} + \beta_{j+1}) \Theta,$$

where $\Theta \in (-0.6, 0.6)$. ϵ_M is the machine precision. An algorithm called (PRO) based on (74) is presented in [Sim84b] or [Fel96].

The values Φ and θ are generated at random and so the algorithm (PRO) may over- or underestimate the real loss of orthogonality. To prevent an underestimation we check the real values of $q_i^T q_j$ from time to time and, if necessary, we switch to the full reorthogonalization strategy. Numerical experiments showed, that this is more efficient than (SO) proposed by Parlett.

4.2 Krylov iteration

The reason why we make use of the Lanczos iteration is the good approximation of the outer eigenvalues by the ritzvalues. This property is very important, whenever directions of negative curvature exist. But if we suppose, that the reduced Hessian of the objective is positive definite, for example in a neighborhood of the solution, then the Lanczos algorithm can be interpreted as a Krylov subspace iteration to solve the Newton equation

$$\nabla^2 f_{\mathcal{F}}(x^k) d = -\nabla f_{\mathcal{F}}(x^k). \tag{75}$$

With the Lanczos method we obtain a good approximation of the Newton direction

$$d^k = -Q_{\nu}^k(T_{\nu}^k)^{-1} Q_{\nu}^k \nabla f_{\mathcal{F}}(x^k) \tag{76}$$

whenever $|\mathcal{N}_-| = 0$. To compute such a truncated Newton direction we do neither need the ritzvalues nor the ritzvectors.

If the ritzvalues are not of interest and only the solution of the symmetric linear system (75) is needed, it is possible to update an initial guess for the Newton direction without the computation of the ritzvectors or -values. Saad presents in [Saa96] a method founded on the Gaussian elimination without pivoting. Unfortunately this method may be sometimes problematic, because it prone to breakdowns.

We used the more sophisticated method called (SYMMLQ) proposed by Paige and Saunders in [PS75]. There the more complex LQ factorization of the tridiagonal matrix T_{ν}^k is adapted step by step with the truncated Newton direction d computed by forward- and backward substitution.

4.3 Control of the Lanczos steps

Whenever the reduced Hessian of the objective function is positive definite and the Lanczos decomposition is used as an iterative solver for the Newton equation (75), we are able to control the maximum number of computed Lanczos vectors \bar{v} . Eisenstat and Walker showed in [EW96] that the inexact Newton method still converges, if the approximated Newton direction d satisfies

$$\|\nabla^2 f_{\mathcal{F}}(x^k)d + \nabla f_{\mathcal{F}}(x^k)\| \leq \mu_k \|\nabla f_{\mathcal{F}}(x^k)\|. \quad (77)$$

Here μ_k is a so-called forcing term and can be chosen

$$\mu_k \stackrel{\text{def}}{=} \gamma \min \left(1.0, \left(\frac{\|\nabla f_{\mathcal{F}}(x^k)\|}{\|\nabla f_{\mathcal{F}}(x^{k-1})\|} \right)^\alpha \right) \quad (78)$$

for some $0 \leq \gamma \leq 1$ and $1 < \alpha \leq 2$. We used $\gamma = 0.9$ and $\alpha = 2$.

To obtain a “better” approximation of the Newton direction, we increase the maximum number of Lanczos vectors \bar{v} by 5 if (77) is violated. Furthermore we reduce it by 3, whenever

$$\|\nabla^2 f_{\mathcal{F}}(x^k)d + \nabla f_{\mathcal{F}}(x^k)\| \leq 0.1\mu_k \|\nabla f_{\mathcal{F}}(x^k)\|$$

holds.

A lower bound on \bar{v} was given by

$$\min \left(|\mathcal{F}|, \min \left(30, \max(10, 10 + (\frac{\ln(|\mathcal{F}|)}{\ln(10)} - 2) \cdot 10) \right) \right)$$

and an upper bound by

$$\min \left(|\mathcal{F}|, \min \left(80, \max(30, 30 + (\frac{\ln(|\mathcal{F}|)}{\ln(10)} - 2) \cdot 25) \right) \right).$$

E.g. in case of $|\mathcal{F}| \geq 10000$ the lower bound is 30 and the upper bound 80.

4.4 Termination criteria

Computation terminates in the following cases

es	Description
-3	The number of iterations was greater than <code>maxiter</code> . The iteration counter increases when the algorithm (BCA) reaches Step 1 .
-2	One of the linesearch algorithms was not able to find a steplength $\sigma \in [\sigma_{\min}, \sigma_{\max}]$ in Step 8 of (BCA).
-1	One of the linesearch algorithms was not able to find a steplength $\sigma \in [\sigma_{\min}, \sigma_{\max}]$ in Step 2 of (BCA).
1	$\ x^k - P_{\Omega}(x^k - \nabla f(x^k))\ \leq \epsilon$ and the approximation of the minimum eigenvalue λ_{\min} was greater than 0 in Step 11 .
2	$\ x^k - x^{k-1}\ \leq \epsilon_x(\ x^k\ + 1)$ for K_x consecutive iterates x^k .
3	$f(x^{k-1}) - f(x^k) \leq \epsilon_f(f(x^k) + \sqrt{\epsilon_M})$ for the last K_f iterates x^k in follow.

4.5 Choice of the parameters

The parameters were chosen as follows

Name	Description	Value
ϵ_M	Machine precision	10^{-16}
ρ	Regularity threshold in (UCA)	10^{-10}
ϵ	Termination parameter in (UCA) and (BCA)	$10^{-6}\sqrt{n}$
η_1	Termination parameter for the projected gradient steps	0.1
η_2	Termination parameter for the second order steps	0.1
l	Maximum number of projected gradient steps without changing the active set	3
δ_1	“Armijo”-parameter used in (LSA1)	10^{-4}
β_1	Backtracking-parameter used in (LSA1)	0.5
δ_2	Parameter used in (LSA2)	0.1
δ_3	Parameter used in (LSA2)	0.9
β_2	Backtracking-parameter used in (LSA2)	0.5
ζ	Safeguard in (LSA2)	-10^{-6}
σ_{\min}	Minimum steplength	10^{-10}
σ_{\max}	Maximum steplength	10^4
ϵ_x	Termination parameter. See <code>es = 2</code>	$10^3\sqrt{\epsilon_M}$
K_x	Termination parameter. See <code>es = 2</code>	10
ϵ_f	Termination parameter. See <code>es = 3</code>	$\sqrt{\epsilon_M}$
K_f	Termination parameter. See <code>es = 3</code>	10
<code>maxiter</code>	Maximum number of iterations. See <code>es = -3</code>	500

5 Numerical results

To test the algorithm (BCA) we use the CONSTRAINED AND UNCONSTRAINED TESTING ENVIRONMENT CUTE. CUTE contains a lot of unconstrained and bound constrained programming problems, coded in a special format called SIF and the necessary tools for decoding the SIF Files and evaluating the objective and the constraints. For more details see [BCGT97].

The computations were performed under LINUX on an Pentium II with 300/66 MHz and 256 MB main memory. The FORTRAN code (double precision) was compiled with g77 -O6 -static. The given data are

Name	Description
<code>name</code>	Name of the problem.
<code>c</code>	Classification of the problem. The problem is unconstrained, if a <code>U</code> is given and bounded if a <code>B</code> is given.
<code>e</code>	Termination status, as described in subsection 4.4.
<code>it</code>	Number of main iterations. The iteration counter increases when the algorithm (BCA) reaches Step 1 .
<code>n</code>	Number of variables. Dimension of x .
<code>nb</code>	Number of active variables in the final point x^e of the iteration.
<code>nf</code>	Number of free variables in the final point x^e of the iteration.
<code>#f</code>	Number of objective function evaluations.
<code>#gf</code>	Number of gradient evaluations.
<code>#hf</code>	Number of Hessian evaluations.
<code>#hfv</code>	Number of reduced Hessian vector products.
<code>%den</code>	Number of nonzeros in the Hessian in percent of n^2 .
<code>norm pgf</code>	Norm of the projected gradient of the objective $\ x^e - P_\Omega(x^e - \nabla f(x^e))\ $ in the final point of the iteration.
<code>lam min</code>	Final minimum eigenvalue approximation of the reduced Hessian computed in Step 11 if <code>es = 1</code> or Step 6 else.
<code>s</code>	Strict complementary condition indicator.
<code>obj.fun</code>	Objective function value $f(x^e)$ in the final point.
<code>time</code>	CPU-time in seconds.

Finally we give a comparison of the results obtained for the problems with dimension greater than or equal to 1000 by our algorithm and the limited memory quasi-Newton method LBFGS-B 2.1. of Nocedal et.al. [BLNZ95]. We used the same termination criteria as given in subsection 4.4 and the maximum subspace dimension in LBFGS-B 2.1. was set to $m = 17$. The given data are

Name	Description
name	Name of the problem.
c	Classification of the problem.
n	Number of variables. Dimension of x .
n.pgf.pl2	Norm of the projected gradient of the objective $\ x^e - P_\Omega(x^e - \nabla f(x^e))\ $ in the final point of our method.
o.fun.pl2	Objective function value $f(x^e)$ in the final point of our method.
t.pl2	CPU-time in seconds needed by our method.
n.pgf.lmqp	Norm of the projected gradient of the objective $\ x^e - P_\Omega(x^e - \nabla f(x^e))\ $ in the final point of LBFGS-B.
o.fun.lmqn	Objective function value $f(x^e)$ in the final point of LBFGS-B.
t.lmqn	CPU-time in seconds needed by LBFGS-B.

6 Conclusion

On balance the result of the numerical experiments is positive. The combination of projected gradient steps and a more sophisticated unconstrained solver, as proposed by Moré and Toraldo, also works effective if second order directions are used in the unconstrained phase. The difficulties in solving for example **HYDC20LS** or **PALMERxy** are either scaling problems or bounds to close to singularities. Most of these programming problems can be solved using a scaling of the variables or more conformed bounds. Note that the algorithm in the implemented version does not make use of any scaling.

An advantage of the implementation is the usage of (**SYMMLQ**) if the reduced Hessian is positive definite. In the case of a strictly convex programming problem the algorithm does not need the computation of any ritzvectors. That is why we achieve the good results in solving **OBSTCLxy** and **TORSIONx**.

Of a special interest is the comparison between our algorithm and the limited memory quasi-Newton method **LBFGS-B** 2.1. of Nocedal et.al. This algorithm (see [BLNZ95]) makes use of limited memory BFGS matrices as presented in [BNS94] and was especially designed for large scale problems. Moreover a gradient projection method, similar to our approach, is implemented to handle the bound constraints. In case of small problems the limited memory quasi-Newton method was faster. But the given results show that the use of second order information makes our approach much more reliable in case of large scale problems. Even by solving problems with a convex objective function, as **JNLBRNGx**, **OBSTCLxy**, and **TORSION6** **LBFGS-B** 2.1. failed.

The performance of (**BCA**) depends strongly on the approximation of the eigenvalues and the truncated Newton direction (76). Therefore the choice of the initial vector for the Lanczos iteration and the control of the number of Lanczos steps is very important. Concerning the convergence analysis the correctness of the eigenvalue approximation can only be assumed. Nevertheless, the numerical experiments show, that the implementation overcomes these difficulties and is very efficient for large scale problems.
